VENDING SYSTEM HAVING BIOMETRIC
VERIFICATION PROTOCOLS FOR USER VERIFICATION

RELATED APPLICATIONS

5 This application is a continuation-in-part of
U.S. Patent Application No. 10/038,445, filed
January 07, 2002 and entitled Vending Machine Having
A Biometric verification System For Authorizing The
Sale Of Regulated Products.

10 BACKGROUND OF THE INVENTION

1. FIELD OF THE INVENTION

 The present invention relates to vending
systems that sell or dispense products directly to
15 the public. More particularly, the present invention
relates to vending systems having identification
verification capabilities to ensure that the person
buying a product from the vending machine is
authorized to receive the product.

20 2. DESCRIPTION OF THE PRIOR ART

 Vending systems are automated systems that
provide a product or service to a customer at the
convenience of the customer. Many vending systems,
25 such as vending machines, require that the customer

pay a fee. However, other vending systems exist, such as ticket kiosks, that vend once a customer verifies their identity.

5 Vending systems are popular because of convenience. Vending systems are ready for business at all times of the day and night. Furthermore, vending systems can be placed in remote locations, such as train stations, hotel corridors and the like that are convenient to customers. However, most all
10 vending machines are non-discriminating. That is, the vending machines will sell a product or service to anyone who deposits the required fee or provides a proper identification code. This is fine with vending machines that sell unregulated products such
15 as candy or soda. However, if a vending system is dispensing products, such as pharmaceuticals, airline tickets or the like, vending systems cannot verify that the person receiving the vended product is truly the person is authorized to receive that
20 product.

 In the prior art, there have been attempts to change the design of vending systems so that the vending machines can only sell products to authorized customers. Such prior art vending

machines are exemplified by U.S. Patent No.
5,722,526 to Sharrard, entitled, Dispensing Security
System For A Vending Machine. In the Sharrard
patent, a vending machine is disclosed that
5 validates the identity of a consumer through an
identification card. The identification card is
inserted into the vending machine. If the
identification card indicates that the customer is
of legal age, the vending machine will vend the
10 regulated product.

Such vending machines have not become
successful because of the obvious flaw in the
verification system. Any person having a valid
identification card can use the vending machine.
15 Accordingly, an underage person can purchase
regulated products from a vending machine just by
borrowing someone else's card. Since the vending
machines verify the card and not the person using
the card, the degree of verification is
20 insufficient.

A need therefore exists for a vending system
that directly verifies the person using the vending
system in a manner that cannot be falsified. This
would enable vending machines to vend regulated

products directly to customers without the fear of abuse by underage or other unauthorized users. This need is met by the present invention as described and claimed below.

5

SUMMARY OF THE INVENTION

10 The present invention is a vending system and its associated method of operation. In the vending system, customers are provided with identification cards. The identification cards can be driver's licenses, bankcards or a specialty vending card. On the identification card is statistical information regarding the identity of the card owner. Also
15 contained on the card is a digital data code corresponding to a biometric characteristic of the card owner.

20 Vending systems are provided that contain card readers and biometric characteristic scanners. When a customer wants to use the vending system, that customer inserts their identification card into the vending system. That customer also subjects themselves to a biometric scan from the biometric characteristic verifier contained within the vending

system.

5 The vending machine reads both the statistical
information from the identification card and the
biometric characteristic data. A systems processor
in the vending system compares the biometric
characteristic data on the identification card with
the biometric characteristic data just gathered by
the biometric scan of the customer. If the data
matches, it can be assumed that the owner of the
10 identification card is using the identification
card. If the identification card then indicates that
the customer is authorized to receive the vended
product, the vending system is enabled and a
regulated product can be sold from the vending
15 system.

BRIEF DESCRIPTION OF THE DRAWINGS

20 For a better understanding of the present
invention, reference is made to the following
description of an exemplary embodiment thereof,
considered in conjunction with the accompanying
drawings, in which:

FIG. 1 is a perspective view of an exemplary

embodiment of a vending machine in accordance with
the present invention;

FIG. 2 is a schematic of the logic components
of the vending machine; and

FIG. 3 is a block diagram logic flow
illustrating an exemplary method of operation for
the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Although the present invention can be added to
any known form of a vending system, such as ticket
kiosk at an airport, or an automated order
dispensing system at a pharmacy, the present
invention is especially well suited for a pay-for-
service vending machine. In the embodiment first
shown, the present invention is shown as part of a
pay-for-service vending machine. Such an embodiment
is merely exemplary and it should be understood that
the present invention can be embodied in many other
forms, depending upon the shape, size and
configuration of the product being vended.

Referring to Fig. 1, a vending machine 10 is shown that vends a product subject to either state or federal regulations. For instance, the vending machine 10 may vend age sensitive products, such as cigarettes, alcohol, adult entertainment, lottery tickets, movie tickets, concert tickets, spray paint, compact discs, DVD's, software, or any other product that may not be sold to minors or young adults under a predescribed age. The vending machine 10 alternatively may vend products such as travel tickets, pharmaceuticals, hunting permits and like products that can only be sold to authorized purchasers.

The vending machine 10 contains a customer interface 12 that contains three separate components. The first component is a money validation unit 14. The money validation unit 14 can be a coin slot and/or paper money acceptor that receives money and validates the value of the money submitted. Such money validation units are commonplace in most all existing vending machines.

The second component of the customer interface 12 is a card reader 16. The card reader 16 can either be a slot or a swipe path that is capable of

reading a digital data code from the magnetic strip
of an identification card 20. The identification
card 20, as will later be explained is a card that
contains both statistical identification parameters
and at least one biometric identification parameter
specific to the owner of the identification card 20.

The third component of the customer interface
12 is a biometric characteristic verifier 18. The
biometric characteristic verifier 18 can be any
device that reads a unique biometric parameter
directly from the person using the vending machine.
The biometric characteristic verifier 18 illustrated
is a fingerprint scanner. The fingerprint scanner
has a pad 19 upon which a person places a finger.
Once a person places his/her finger on the pad 19,
the print on the finger is electronically scanned.
Although a fingerprint scanner is illustrated, it
should be understood that other biometric
characteristic verifiers can be used. Other
biometric characteristic verifiers include, but are
not limited to, retina scanners, face recognition
systems, knuckle scanners, palm scanners, voice
print recognition systems and the like. Many such
biometric characteristic verifiers exist in the art

of biometric identification. Many such biometric characteristic scanners can be adapted for use with the present invention.

5 A customer is instructed on how to use the vending machine 10 through instructions. The instructions may be printed on the vending machine 10. However, in a preferred embodiment, instructions are provided via an electronic display 28.

10 In addition to the customer interface 12, the vending machine 10 also includes a product selection display 24 and product selection controls 26. The product selection display 24 identifies the product selection controls 26. A customer uses the product selection controls 26 to select a product from the vending machine 10.

15 In Fig. 1, an identification card 20 is also shown. The identification card 20 contains two types of information. The first type of information is statistical information about a person, such as name, address, age and the like. The second type of information contained on the identification card 20 is at least one biometric parameter unique to the owner of the card. For instance, the identification card 20 can contain data that represents the

fingerprint, retina scan, face recognition scan, or the like of the card owner.

The information stored on the identification card is stored in the form of a digital data code. In this manner, the information cannot be viewed by a casual observer or copied using any print copy techniques.

The identification card 20 can be a custom card produced by a private company, such as a credit card company. However, states, such as the State of Pennsylvania, have announced that they will be adding biometric parameter data to driver's licenses in the future. Any such identification card distributed by the government can also be used.

Referring to Fig. 2, it can be seen that the money validation unit 14, the identification card reader 16, the biometric characteristic verifier 18 and the product selection controls 26 are all interconnected with a systems processor 30. The systems processor 30 is also connected to the various dispensing mechanisms 32 contained within the vending machine and the optional electronic display 28. Before the systems processor 30 activates any of the dispensing mechanisms 32, a

proper sequence of events must occur that involves the money validation unit 14, card reader 16, biometric characteristic verifier 18 and product selection controls 26.

5 Referring to Fig. 3, the method of operation for the vending machine system is disclosed. As is indicated by Block 40, a customer first inserts money into the money validation unit 14 (Fig. 1). The amount of money inserted must equal or surpass
10 the price set for the regulated product that is to be sold.

 Once the proper fee has been deposited, the customer is prompted to insert their identification card 20 (Fig. 1) into the identification card reader
15 16 (Fig. 1). This is indicated by Block 42. As shown by Block 44 and Block 46, respectively, the card reader reads the demographic data and the biometric data from the identification card. The demographic data can contain the age of the person as well as
20 other information, such as name, customer number, driver's license number or the like that can be used to identify that person. The biometric data can be any set of data representative of a biometric characteristic. As has been previously mentioned,

this can be a fingerprint, voice print, retina scan, face recognition scan or any other unique biometric parameter.

5 Once the statistical and biometric data is read from the identification card, the person using the vending machine is then prompted to engage the biometric characteristic verifier 18 (Fig. 1) on the vending machine. This step is shown by Block 48. This may include placing a finger on a scan pad,
10 standing still for a face recognition scan or some similar process.

 As is indicated by Block 50, the systems processor 30 (Fig. 2) within the vending machine first reads the statistical data gathered from the identification card. If the demographic data
15 indicates that the person is underage or otherwise not authorized for the purchase, the vending machine does not permit the sale and the money is returned.

 However, as indicated by Block 52, if the
20 demographic data contained on the identification card does indicate that the sale is permissible, the systems processor then reads the biometric data from the identification card and compares that data to the data collected directly from the biometric

characteristic verifier. If the biometric data contained on the identification card matches the data collected directly from the biometric verifier, it is safe to assume that the person who possesses the identification card is the authorized owner of that identification card. As such, the vending machine vends the selected product. See Block 54. However, if the biometric data contained on the identification card does not match the data collected directly from the biometric verifier, it can be assumed that an unauthorized person has possession of another's identification card. The vending machine will then refuse to sell the regulated product.

15 The present invention vending machine ensures that only authorized persons can purchase products from the vending machine. As such, regulated products can be sold through vending machines without the fear of use from underage or otherwise unauthorized persons.

20 In the described embodiments that are illustrated, the vending machine is a pay-for-service vending machine where a customer pays money into the vending machine. Other vending systems

exist that are not pay-for-service. Rather, the vending systems distribute products that have been prepaid for in a different transaction. For example, ticket kiosks at airports and train stations print tickets that have been prepaid. The user of the vending system need only provide the proper identification that they are the person who has prepaid for the service.

The present invention can be applied to such vending systems. In the application of the present invention, the previously described steps of paying money into the vending system can be eliminated. Rather, the vending system would require the use of an identification card and biometric scanner so that the identity of the user can be confirmed in the same manner as has been previously described.

Thus, it will be understood that the embodiment of the present invention vending system illustrated is only exemplary. There are hundreds of different makes and models of vending systems. Some are pay-for-service, some are not. The present invention verification system can be adapted for use in any such vending system. All such modifications are intended to be included within the scope of the

present invention as defined by the appended claims.
